A Field experiment was conducted in a fine loamy mixed Hyperthermic Typic Haplustept soil to study the effect of fly ash and FYM on yield of rice and on cracking pattern of soil. The grain and straw yield of rice was significantly increased with fly ash, FYM and their interactions. The highest grain ( $5.84 \text{ t ha}^{-1}$ ) and straw yields ( $7.87 \text{ t ha}^{-1}$ ) were recorded by combined application of fly ash at  $10 \text{ t ha}^{-1}$  and FYM at  $10 \text{ t ha}^{-1}$  which was on par with fly ash at  $15 \text{ t ha}^{-1}$  along with FYM at  $10 \text{ t ha}^{-1}$ . Application of fly ash and FYM has resulted in lesser number of cracks with more width and depth when compared to control. Study of cracking pattern of the field after crop harvest indicated that the number of cracks ( $29.33 \text{ m}^{-2}$ ) were lowest and the width of cracks (3.67 cm), depth of cracks (10.57 cm) were highest in  $\text{FA}_{15} \text{ FYM}_{10}$  followed by  $\text{FA}_{10} \text{ FYM}_{10}$  ( $38.67 \text{ m}^{-2}$ , 2.87 cm, 8.7 cm, respectively) when compared to control ( $\text{FA}_0 \text{ FYM}_0$ ) ( $96.67 \text{ m}^{-2}$ , 0.78 cm, 3.57 cm, respectively). The aggregate stability studied in terms of per cent aggregates  $> 0.25 \text{ mm}$  in diameter (55.60) and mean weight diameter (1.7) were highest in  $\text{FA}_{15} \text{ FYM}_{10}$  followed by  $\text{FA}_{10} \text{ FYM}_{10}$  (53.40 and 1.95 respectively) when compared to control (43.63 and 1.79, respectively).

### Introduction

Fly ash is formed from burning of pulverized coal at electric power generating plants. Finding local outlets for sufficient quantities of fly ash often create problem of disposal. One of the ways of effective utilization of fly ash could be its use as a soil amendment and as a source of plant nutrients. Physically fly ash occurs as very fine particles, having an average diameter of  $< 10 \text{ mm}$ , low to medium bulk density, high surface area and very light texture. Chemically the composition of fly ash varies depending on the quality of coal used and operating conditions of thermal power stations (Sahoo and Kar, 1998). Approximately on an average 95 to 99 percent

of fly ash consists of oxides of Si, Al, Fe and Ca and about 0.5 to 3.5 per cent consists of Na, P, K and S and the remainder of the ash composed of trace elements.

Rice plays a pivotal role in Indian economy being the staple food for two thirds of the population. In India, it is grown in an area of 42.2 million hectares with a production of 91.0 million tones and productivity of  $2154 \text{ kg ha}^{-1}$ , while in Andhra Pradesh it is grown in an area of 39.8 lakh hectares with a production of 117.0 lakh tones and productivity of  $2939 \text{ kg ha}^{-1}$ .

The crack size and spacing that is their network in the field indicates the hydrodynamics properties of soil. Study on cracking pattern is a simple test which indicates the general swell shrink behaviour of the soil. During fallow phase of cultivation cracking pattern decides the water loss from the soil mass particularly from the deeper layers. The present investigation was under taken to study the integrated effect of fly ash and FYM on yield of rice and on cracking pattern of soil.

### **Materials and Methods**

A field experiment was conducted in a fine loamy, mixed Hyperthermic Typic Haplustept soil at College farm, Department of Soil Science and Agricultural Chemistry, College of Agriculture, Acharya N.G. Ranga Agricultural University, Rajendranagar. The experiment comprised of eight treatment combinations with four levels of fly ash (0, 5, 10 and 15 t ha<sup>-1</sup>) and two levels of FYM (0 and 10 t ha<sup>-1</sup>). Fly ash and FYM applied as per the treatments before transplanting the rice. All the plots have received the common doses of NPK fertilizers (120-60-40 kg ha<sup>-1</sup>). The rice var. Tellahamsa was used as the test crop.

The fly ash was collected from National Thermal Power Corporation (NTPC), Ramagundam, Andhra Pradesh. It contained the nutrients like N (27.5 mg kg<sup>-1</sup>), P<sub>2</sub>O<sub>5</sub> (29.6 mg kg<sup>-1</sup>), K<sub>2</sub>O (110.5 mg kg<sup>-1</sup>), S (25.4 mg kg<sup>-1</sup>), Ca (7.25 mg kg<sup>-1</sup>), Mg (2.20 mg kg<sup>-1</sup>), Fe (17.50 mg kg<sup>-1</sup>), Mn (3.34 mg kg<sup>-1</sup>), Cu (0.98 mg kg<sup>-1</sup>), Zn (1.83 mg kg<sup>-1</sup>). The texture of fly ash was silty loam with pH 8.1 and EC 0.37 dS m<sup>-1</sup>. The experimental soil was sandy clay loam in texture, slightly alkaline in reaction (pH 7.9), non saline (EC 0.29 dS m<sup>-1</sup>), low available N (210 kg ha<sup>-1</sup>), available phosphorus (8.7 kg P<sub>2</sub>O<sub>5</sub> ha<sup>-1</sup>), medium in available potassium (180 kg K<sub>2</sub>O ha<sup>-1</sup>), and

sufficient in micronutrient status (Fe 8.62 mg kg<sup>-1</sup>, Mn 5.56 mg kg<sup>-1</sup>, Cu 1.09 mg kg<sup>-1</sup> and Zn 1.05 mg kg<sup>-1</sup>).

Grain and straw yields of rice were recorded at harvest. Effect of different levels of fly ash and FYM on cracks distribution pattern was studied about one month after harvest of the rice crop and evaluated in terms of number of cracks per m<sup>2</sup>, width of cracks and depth of cracks. Soil samples were collected from 0 to 15 cm depth in each sub plot after the harvest of the crop. The composite samples were analyzed for water stable aggregates (Aggregates > 0.25 mm in diameter) by Yoders Wet Sieving method (Kemper and Chepil, 1965). Mean weight diameter was worked out as per the formulae given by Van Bavel (1949).

### **Results and Discussion**

#### **Yield of rice**

Fly ash, FYM and their interactions showed significant influence on grain and straw yield of rice (Table 1). The highest grain yield was recorded by FA<sub>10</sub> FYM<sub>10</sub> (5.84 t ha<sup>-1</sup>) which was on par with FA<sub>15</sub> FYM<sub>10</sub> and has recorded about 21 per cent higher grain yield over control (FA<sub>0</sub> FYM<sub>0</sub>) (4.82 t ha<sup>-1</sup>). Similarly the increase in grain yield of rice due to application of fly ash was reported by Arvind Kumar *et al.*, (1998) and Jayabal *et al.*, (2000). The highest straw yield was reported by FA<sub>10</sub> FYM<sub>10</sub> (7.87 t ha<sup>-1</sup>) which was on par with FA<sub>15</sub> FYM<sub>10</sub> and has recorded about 17.8 per cent higher straw yield over control (FA<sub>0</sub> FYM<sub>0</sub>) (6.68 t ha<sup>-1</sup>). The results obtained are in confirmation with those obtained by Arvind Kumar *et al.*, (1998), Mongia *et al.*, (2003).

The supply of nutrients, conducive to physical environment leading to better aeration, root activity and nutrient absorption and the

consequent complementary effect would have resulted in higher grain and straw yield of rice (Selvakumari *et al.*, 2000).

### Cracking pattern of soil

The number of cracks per m<sup>2</sup> and mean width

of cracks after the rice crop harvest was significantly influence by fly ash levels, FYM and their interaction where as depth of cracks was not significantly influenced by FYM application (Table 2, Fig. 1 and 2). The control treatment (FAo FYMo) has recorded maximum number of cracks per m<sup>2</sup> (96.67).

**Fig.1** Effect of fly ash levels without FYM on cracking pattern under field conditions

**Fig.2** Effect of fly ash levels with FYM (10 t ha<sup>-1</sup>) on cracking pattern under field conditions

The minimum numbers of cracks were recorded in FA<sub>15</sub> FYMo (29.33). Whereas the highest mean width of cracks (3.67 cm) and the highest mean depth of the cracks (11.03 cm) was recorded in FA<sub>15</sub>FYMo compared to 0.78 cm width and 3.57 cm depth in control. Thus application of fly ash and FYM has resulted in lesser number of cracks with more width and depth when compared to control. As physically fly ash occurs as a very fine particles having an average diameter < 10 mm with high surface area, its application might have modified the soil physical environment resulting in deep and wide cracks. Higher proportion of fine particles results in bigger but less number of cracks (Prabhu Prasadini, 1989). The deep and wide cracks in fly ash applied plots decide the water loss from the soil mass particularly from the deeper layers. The quick water loss in coastal areas provides easy tillage operations, which is suitable for growing pulses in coastal areas during *Rabi* season. So fly ash application reduces submergence in coastal lands and provides drying conditions.

### **Aggregate stability of soil**

It was studied in terms of per cent of aggregates greater than 0.25 mm in diameter and mean weight diameter of soil at crop harvest. The treatment FA<sub>15</sub> FYM<sub>10</sub> has recorded the highest per cent of aggregates > 0.25 mm in diameter (55.6 %) followed by FA<sub>10</sub> FAM<sub>10</sub> (53.4 %) compared to 43.63 per cent in control (Table 3). The mean weight diameter (MWD) was not significantly influenced by fly ash but was significantly influenced by FYM. Application of FYM at 10 t ha<sup>-1</sup> has recorded MWD of 1.92 when compared to 1.77 in FYMo. In general per cent aggregates and MWD was more influenced by FYM application than fly ash application.

Craini (1988) has reported that fly ash had significant effect on MWD. As it is well

known that organic manures play role in soil aggregation, there by maintains favorable physical conditions and supply polysaccharides which are vital for improvement of soil structure. Thus the FYM might have helped in improving the soil aggregate stability.

Study on relationship between aggregate stability and cracking pattern showed that the number of cracks were negatively correlated with per cent aggregates > 0.25 mm in diameter (-0.55) and MWD (-0.21). However the correlations were not significant. The width of cracks was significantly and positively correlated with MWD (0.81) and depth of cracks was not found to be significantly correlated with per cent aggregates > 0.25 mm in diameter (0.47) and MWD (0.03).

In conclusion, taking into consideration of grain yield, application of fly ash at 10 t ha<sup>-1</sup> along with FYM at 10 t ha<sup>-1</sup> is recommended for rice crop grown in Typic Haplustept soils of the Southern Telangana Zone of Andhra Pradesh.
