The present investigation entitled, “Suitability of Cut Corms as Planting Material on Flowering, Corm and Cormel Production in Gladiolus (Gladiolus grandiflorus L.) Varieties” was under taken in the Department of Horticulture, Naini Agricultural Institute, Sam Higginbottom University of Agriculture, Technology and Sciences, Allahabad during Rabi season (2016-2017). The experiment was layout in Factorial Randomized Block Design (FRBD) with 12 treatments and each treatment replicated thrice. The treatments consist of different division of corms (Full, Half and one-third) and 4 varieties (Deepest Red, Jessica, Amsterdam and Esta Bonita). Early spike emergence (55.27) was found when full corm was planted for Jessica Variety whereas spike length was maximum (94.00cm) in variety Esta Bonita. Regarding number of florets per spike (14.83), number of daughter corms (65.16) per plant was found to be best in variety Amsterdam when full corms were planted whereas number of cormels (59.57) was found to be maximum in variety Deepest Red.

Introduction

Gladiolus is a popular flowering plant grown all over the world, from South Africa to West Asia. The term gladiolus was coined by Pliny the Elder (A.D-23-79) deriving from the Latin word “Gladius”, because of its sword-like leaves. It is popularly known as sword lily. The modern hybrids are botanically known as Gladiolus grandiflorus belonging to family Iridaceae bearing chromosome number 60. It is also known as “Queen of Bulbous Crops”. Unlike other export oriented cut flower it can be raised under open field conditions and still produces exportable quality spikes. It is easy to grow and is commonly grown for garden use and for cut flower (Aswath and Parathasarthy, 1996). In the international cutflower trade gladiolus occupies fourth place (Bhattacharjee and De, 2010). Gladiolus is grown commercially from corms both for the flowering spikes and for corm production and it is principally propagated by natural multiplication of new corms and cormels (Memon et al., 2009; Hartman et al., 1990; Ziv and Lilien-kipnis, 1990). However, owing to their low rate of multiplication and to a high percentage of spoilage of corms during storage, there is an insufficient supply of planting material (Memon et al., 2012; Singh and Dohare, 1994). In such a case, propagation may be done by cutting the corms...
into several pieces to increase the number of planting material. The segment of corm to be used as a propagule should have at least one eye and a portion of basal plate or root zone. Better results can be obtained when radial cuts are made the corms are cut 7 to 10 days before planting. Small corms can be divided into 3 to 4 pieces while the large one can be divided into 7 to 10 pieces (Gromov, 1972) which helps in providing benefits to the growers in increasing the planting materials.

Materials and Methods

Experimental site and duration

A field experiment entitled was conducted at Horticultural Experimental Field, Department of Horticulture, Sam Higginbottom University of Agriculture, Technology and Sciences, during Rabi season of 2016-17 from November to April.

Experimental design

4 x 3(4 varieties x 3 corm sizes) factorial experiment was laid out in a Factorial Randomized Block Design with 3 replications.

Treatments of the experiment

Gladiolus variety (V1: Deepest Red; V2: Jessica; V3: Amsterdam; V4: Esta Bonita) and corm sizes (C0: whole corm; C1: Half size corm; C2: one-third corm size) were used in the experiment.

Plot size

The size of unit plot was 2 m x 2m.

Procedure for the application of treatments

Few corms were cut into two sections and few into three sections retaining abud with each section. Bavastin was applied to the segments and whole corm to prevent fungus. Then the segments and whole corms are treated with GA3 to break dormancy.

Planting of the corms

Corms were planted at 5 cm depth in the plot maintaining 30cm x 20 cm spacing. In each plot, 20 corms were planted.

The different treatment combinations are as follows

T1 (V1C0) Deepest Red x Full size corm; T2 (V1C1) Deepest Red x Half size corm; T3 (V1C2) Deepest Red x One-third corm size; T4 (V2C0) Jessica x Full size corm; T5 (V2C1) Jessica x Half size corm; T6 (V2C2) Jessica x One-third corm size; T7 (V3C0) Amsterdam x Full size corm, T8 (V3C1) Amsterdam x Half size corm; T9 (V3C2) Amsterdam x One-third corm size; T10 (V4C0) Esta Bonita x Full size corm; T11 (V4C1) Esta Bonita x Half size corm; T12 (V4C2) Esta Bonita x One-third corm size

Results and Discussion

Floral parameters

Number of days taken for spike emergence

Interaction effect revealed that minimum number of days taken for spike emergence (55.27) was recorded in T4 followed by T1 (72.33) whereas maximum number of days was in T12 (100.43).

Large size corm helps the plant for growth and development with supplying storage nutrients in the corm which is the ultimate result of minimum days for emergence of spike. Similar findings were also found by Bhat et al., (2009) in gladiolus.
Spike length (cm)

Interaction effect revealed that maximum spike length (94.00cm) was recorded in T_{10} followed by T_{7} (83.40cm). The spike length was found to be minimum in T_{6} is 41.91cm. This might be due to the higher amount of stored food material from large corm which resulted in larger spike length. Similar results were also reported by Dod et al., (1989) and Bhattacharjee (1981) (Table 1).

Number of florets per spike

Interaction effect revealed that maximum number of florets per spike (14.83) was recorded in T_{7} followed by T_{10} (12.63) whereas minimum in T_{6} (7.63). Plant height and spike length had direct influence on number of florets per spike and improvement in spike length and plant height directly increased number of florets per spike. Similar findings were given by Mahesh et al., 2011 (Table 2).

Diameter of basal floret (mm)

Interaction effect revealed that maximum diameter of basal floret (125.42mm) was recorded in T_{10} followed by T_{7} (112.62mm). The diameter of minimum in T_{6} is 67.74mm. Diameter of florets indicating that with the increment of plant height this associated character could be improved (Kumar et al., 2011).

Yield parameters

Weight of daughter corms (g)

Interaction effect revealed that maximum weight of daughter corms (52.85g) was recorded in T₇ followed by T₁₀ (48.43g) whereas minimum in T₆ (18.93). This may be attributed to the good vegetative growth of plants in initial stages, which provides good amount of photosynthates for storage in corms. It may be mentioned here that when the half corm or whole corm were planted, the innermost corms developed on the terminal bud were larger and heavier than the outer corms which were smaller and lighter, implying that the available food materials were first translocated to the central corms and thereafter to the laterals. Similar results were given by Mahasen et al., 2015 (Table 3)

Number of cormels per plant

Interaction effect revealed that maximum number of cormel formed per plant (59.57) was recorded in T₁ followed by T₂ (41.73) whereas minimum in T₆ (8.63). The result is in an agreement with the findings of Joshi et al., (2011)

On the basis of present investigation early spike emergence was found in V₂ (Jessica) whereas spike length was best in V₄ (Esta Bonita) followed by V₃ (Amsterdam). Regarding number of florets per spike, no. of daughter corms per plant was found to be best in V₃ (Amsterdam). Full corms were found to be best in terms of all vegetative and floral parameters but in terms of corms and cormel production cut corms were found to be better. So cut corm can be used for commercial gladiolus production and this might reduce the cost for planting materials.

Acknowledgement

We authors are greatly thankful to other professors and members, Department of Horticulture, Naini Agricultural Institute, for their guidance and support during the research trail and also thankful to Department of Soil Science and Department of Agro- metrology for their information.
