A B S T R A C T

The present investigation was conducted at Horticultural Research Station, Anantharajupeta, Dr. Y.S.R Horticultural University, Andhra Pradesh during 2014-2015. The trail was carried out in capsicum cv. Solan Bharpur consisting of 11 treatments, replicated thrice with Randomized Block Design. The results revealed that, capsicum plants applied with 10 t/ha of well rotten farm yard manure (T_{10}) recorded significantly taller plant (87.30 cm), number of leaves (163.77), stem girth (4.85 cm), leaf length (19.04 cm), leaf width (11.33 cm). However, higher number of fruits (25.66), fruit length (8.83 cm), fresh fruit weight (58.83 g), weight of 10 fruits (663.72 g), yield (16.32 t/ha), pericarp thickness at the blossom end (1.33 cm), number of seeds per fruit (140.05), dry weight of 100 seeds (0.71 g), fruit diameter (18.25 cm) and pericarp thickness at the centre of the fruit (0.81 cm) were registered with the application of vermicompost (2.50 t/ha) (T_9).

Introduction

Sweet pepper (*Capsicum annum* L.) is a member of family solanaceae and genus capsicum. Tropical South America, especially Brazil is thought to be the original home of pepper. It is now widely cultivated in Central and South America, Peru, Bolivia, Costa Rica, Mexico, in almost all the European countries, Hong Kong and India. In India it is cultivated commercially in Tamil Nadu, Karnataka and Himachal Pradesh and in some parts of Uttar Pradesh.

Organic fertilizer is the key to improve the sustainability of agricultural farming system and soil productivity. It has been proved that indiscriminate use of inorganic fertilizers results in decrease in soil fertility and increase in soil acidity with depletion of organic humus content in addition to poor crop quality. Use of organic manures to meet the nutrient requirements of crop would be an inevitable practice in the years to come for sustainable agriculture since organic manures not only improve the soil physical, chemical and biological properties (Heitkamp *et al.*, 2011) but also improves the moisture holding capacity of soil, thus resulting in enhanced crop productivity along with better quality of crop produce (Premsekhar and Rajashree, 2009). Micronutrients play vital roles in the growth and development of plants, due to their stimulatory and catalytic effects on metabolic

processes and ultimately on flower yield (Lahijie, 2012) and quality (Khosa *et al.*, 2011). The growth parameters like plant height and number of branches plant^{-1}was found maximum with combined application of vermicompost, FYM and urea at 50 per cent level. The yield attributes including fruit yield was found maximum with nitrogen received from vermicompost and urea at 50 per cent level. Improvement in qualitative aspects was increased with the application of neem cake compared to other inorganic sources (Pariari and Khan, 2013).

Vermicompost is a rich source of vitamins, hormones, enzymes, macro and micronutrients which when applied to plants help in efficient growth (Prabhakaran, 2005). The growth rate is fast due to increased uptake of macro and micronutrients present in the vermicompost, which results in increased shoot length and number of leaves in vermicompost applied plants. Vermicompost being rich in NPK and other nutrients can be used as a substitute for chemical fertilizer (Jeyabal and Kuppuswamy, 2001).

Application of micronutrients *viz.*, zinc, boron, magnesium and organics *viz*., vermicompost and FYM bring profound changes in various metabolic processes within the plant system thereby influence the yield considerably. In recent years, the roles of these micronutrients are gaining more importance particularly in capsicum to boost not only the productivity but also to improve the quality. Hence, an investigation on the effect of micronutrients and organics on growth and quality of capsicum under shade net conditions was initiated.

Materials and Methods

A field experiment entitled "Influence of micronutrients and organics on growth and yield of capsicum cv. Solan Bharpur under shade net condition" was conducted during rabi season of 2014-15. The experiment was carried out at Horticultural Research Station, Anantharahjupeta, Y.S.R Kadapa Dist. Andhra Pradesh. The experimental field was laid out in Randomized Block Design with 11 treatments with three replications. The details of experimental treatment plan employed in the present investigation was carried out as follows: T_1-$ZnSO_4$ (25 kg/ha), T_2-$ZnSO_4$ (0.2%), T_3-Borax (10 kg/ha), T_4-Borax (0.2%), T_5-$MgSO_4$ (10 kg/ha), T_6-$MgSO_4$ (0.2%), T_7-$FeSO_4$ (10 kg/ha), T_8-$FeSO_4$ (0.2%), T_9-Vermicompost (2.50 t/ha), T_{10}-FYM (10 t/ha) and T_{11}-Control (No application of any nutrients).

After ploughing and digging, the land was brought to fine tilth under shade net house. All weeds were completely removed from the field. All the stubbles of previous crop were removed from the field and burnt. The trial was conducted in red loam soil with a spacing of 60 x 60 cm and planting was done with 45 days old healthy seedlings during November, 2014. The experimental plots were of size 2.50 × 2.50 m and each plot consisted of size ridges with 20 cm spacing. The soil of the experimental field was red loam in texture with pH 7. 2. Necessary plant protection measures were followed to prevent pest and disease incidence. Well decomposed farmyard manure @ 10 t ha^{-1} and vermicompost @ 2.50 t ha^{-1} was applied uniformly as per the treatment and mixed well. The manures were incorporated in the respective plots 20 days before planting when applied as basal. Recommended micronutrients *viz*., Zn, Bo, Mg and Fe are applied as basal dose as per treatment and foliar feeding for two times once at fruit setting and again at fruit development stage. At initial stage of growth, spinosod @ 0.2 ml l^{-1} was sprayed to manage sucking pests and *Spodoptera litura,* while no disease incidence was noticed during the investigation period. For recording

observations, five plants were selected per each plot at random and were labelled properly by indicating treatments. The data were analysed using the procedure outlined by Panse and Sukhatme (1985).

Results and Discussion

The perusal of data presented in Table 1 clearly indicated that plant height (87.30 cm), number of leaves (163.77), stem girth (4.85 cm), leaf length (19.04 cm) and leaf width (11.33 cm) recorded was maximum with the application of FYM @ 10 t ha^{-1}. Number of branches per plant was not significantly influenced by treatments. Similar types of results have also reported by Sahoo *et al.*, (2017) in sweet pepper and Reddy *et al.*, (2017) in chilli. The good plant growth, number of leaves and higher leaf length and width may be due to application of FYM which might have acted as a source of additional nutrients and moisture supply. The earlier study made by Patil *et al.*, (2014), Singh *et al.*, (2014), Omogoya and Adewale (2015) also reported application of FYM and other organic manures significantly influence the growth and development of capsicum.

Data furnished in Table 2 and 3 shows that higher number of fruits (25.66), fruit length (8.83 cm), fruit diameter (18.25 cm), fresh fruit weight (58.83 g), weight of 10 fruits (663.72 g), yield (16.32 t/ha), pericarp thickness at the blossom end (1.33 cm), number of seeds per fruit (140.05), dry weight of 100 seeds (0.713 g) and pericarp thickness at the centre of the fruit (0.81 cm) were recorded with the application of vermicompost (2.50 t/ha).Vermicompost used in this treatment is known to enhance microbial activity, which may have improved availability of macro and micro nutrients to the plants. It also acts as a chelating agent and regulates availability of metabolic micro nutrients to plants and, thus helps increase yield attributing traits by providing nutrients in their available form.

Besides, vermicompost also contains significant quantities of nutrients, a large amount of beneficial microbial populations and biologically active metabolites particularly gibberellins, cytokinins, auxins and vitamins (Bhavalkar, 1991) all of which have a beneficial effect on photosynthesis and translocation.

Results of the present findings are in agreement with findings of several earlier workers *viz*. Jeevansab (2000), Salas and Ramirez (2001), Basavaraja *et al.,* (2003) and Ganiger *et al.,* (2012) in capsicum (bell pepper).

Organic manures increases the availability of nutrients, especially protein synthesis further it was suggested that significantly increase in number of fruits and fresh, dry weight of fruit weight might have accelerated the mobility of photosynthetic from source to the sink which was influenced by the growth hormones which released from Vermicompost, the organic sources. Similar findings were reported by Dileep and Sasikala (2009), Deshpande *et al.,* (2010), Singh *et al.,* (2014), Jayanti *et al.,* (2014), Mudiganti *et al.,* (2015) in chilli and Jamir *et al.,* (2017) in sweet pepper. Congenial environment prevail under shade net house might also favours for good growth and yield of capsicum cv. Solan Bharpur.

Application of nutrients like Vermicompost and FYM has a significant and vital effect on growth, yield and quality attributes of capsicum. The supply of various plant nutrients at an optimum level sustains the desired crop productivity by optimizing the benefit from all sources in an integrated manner. The inference drawn from the present investigation clearly stated that organics are effective alternatives as a source of macro- and micronutrients and have a potential to improve yield, and thus avoid costly chemical fertilizers. The bio-organic technology is based on eco-biotechnological approaches utilizing the bio-transformation of energy rich and complex organic substances into bio-stabilized composed products.
