**ABSTRACT**

**Introduction**

Bacterial leaf blight disease caused by *Xanthomonas axanopodis* pv. *alii* (Xaa) is an important disease on onion (Kadota *et al.*, 2000; Roumanag *et al.*, 2004; Habazar *et al.*, 2007). Loss of the yield due to the attack of this pathogen can reach 100% especially if suitable environment (Schwart and Gent, 2006). In Indonesia, information about controlling this pathogen is still limited. For this reason, it is necessary to develop various research methods that environmentally friendly, one of which is to use a biopesticide derived from *Trichoderma* spp.

*Trichoderma* is one of the soil fungi that is antagonistic to various pathogens that cause plant disease (Cook and Baker, 1983; Nurbailis, 1992; Harman, 2006; Pusvapavathi *et al.*, 2016). This mechanism of antagonism...
is competition, mycoparasites, and antibiosis (Cook and Baker, 1983; Howell, 2003; Nurbailis, 2008). Nurbailis et al., (2006) reported that T. viride and T. harzianum isolates from banana rhizosphere were able to inhibit the growth of F. oxysporum f.sp. cubense with the antibiosis mechanism.

Antibiosis is a mechanism of antagonistic fungi that can inhibit the growth of pathogens with antagonistic chemical products that produced and released by Trichoderma into their environment. There are extra cellular enzyme systems, antibiotics which damage the pathogens (Cook and Baker 1983; Leelavathy et al., 2014) Antibiotic compounds can be used as an alternative to substituting artificial pesticides for controlling plant pathogens

Trichoderma spp produces secondary metabolites which act as antifungal and antibacterial such as polyketides, pyrones, and terpenes (Nahe et al., 2014). Leelavathy et al., (2014) reported that crude extracts of T. harzianum with different concentrations can inhibit the growth of various pathogenic bacteria. Effective concentration in inhibiting the growth of Staphylococcus aureus, Escheria coli and Klebsiella was 100 µl / ml with clear zone area 1.8 - 2.0 cm. Basiriya et al., (2017) report that secondary metabolites (crude extract) from Trichoderma spp indigeneos mangrove rhizosphere inhibited the growth of S. aureus, E. coli and Pseudomonas auregenesa. The best isolates were T. harzianum (1) and T. viride.

The development of using Trichoderma spp which indicates the presence of an antibiosis mechanism for controlling Xaa on red onion requires the research about Utilization of secondary metabolites from Trichoderma spp to inhibit the growth of Xaa. The purpose of this research were to obtain superior Trichoderma isolates which is capable to produce secondary metabolites which act as antibacterial compounds and the best concentration for inhibiting the growth of Xanthomonas axonopodis pv. allii.

**Materials and Methods**

The research was conducted at the Microbiology laboratory of the Faculty of Agriculture Andalas University, Padang from April to November 2018. This research used factorial in Complete Randomized Design which consist of 2 factors, 15 treatment combinations and 3 replications was employed in this study. The first factor was the filtrate (secondary metabolite) of Trichoderma spp, ie: T. viride, T. harzianum and Trichoderma PP3. The second factor were the filtrate concentration which consist of 0%, 25%, 50%, 75% and 100%. The data were analyzed by variance and with continued Duncan's multiple distance test (DNMRT) at a 5% significance level

**Implementation**

**Propagation of Trichoderma spp.**

Trichoderma spp.: T. viride, T. harzianum, T. koningii, which had been shown antibiosis mechanism, were propagated in Potato Dextrosa Agar medium and incubatedin room temperature for 7 days.

**Propagation of Trichoderma spp in liquid culture**

Trichoderma was propagated in liquid culture in Potato Dextrosa Broth medium. For every 1 liter of medium used as much as 100 ml of starter (10% total volume) and incubated for five days at room temperature, then the culture was incubated using a shaker at a speed of 180 rpm for 7 days. (Kumar et al, 2014).
Preparation of secondary metabolite of Trichoderma spp

Trichoderma spp were propagated in a liquid medium as mentioned above, used to obtain filtrate by separating the liquid culture between the hifa and the filtrate by using What man filter paper, then centrifuged at 4000 rpm for 30 minutes. The filtrate was filtered again with What man paper into another test tube, finally a milipore filter membrane (0.2 µm) was used for filtering the filtrate.

Preparation of Xanthomonas axonopodis pv. allii Culture

Xanthomonas axonopodis pv. allii was obtained from the collection of the Laboratory of Microbiology, Faculty of Agriculture, Andalas University, were rejuvenated on Nutrient Glucose Agar (NGA) medium by scratching method and incubated for 48 hours at room temperature

Treatment of Trichoderma filtrate against Xanthomonas axonopodis pv. allii

Trichoderma filtrate was prepared with various concentrations, each of filtrate was taken 1 ml and mixed evenly with 9 ml of NGA medium which was still hot (45°C), then the medium was cooled. The Xanthomonas saxonopodis pv. allii (10^4 cells / ml), Spread on the medium and incubated for 48 hours at room temperature.

Testing of Xanthomonas axonopodis pv. allii growth inhibition carried out by using sterile disc paper, filter paper is cut circularly with a diameter of 0.5 cm, soaked into each filtrate for 5 minutes, placed on streaks of Xanthomonas axonopodis pv. allii in petri dishes and incubated for 24 hours at room temperature, for a control was used sterile aquades.

Observation

Inhibitory Power of Trichoderma Filtrate against X. axanopodis pv. allii Growth

The inhibitory power of Trichoderma filtrate against X. axanopodis pv. Allii X. axanopodis pv. allii growth is done by carving a clear zone formed on paper discs that contain Trichoderma spp filtrate. Measurements are made by drawing the area of the clear zone formed on transparent plastic and measured with a ruler.

Number of X. axanopodis pv. allii colonies by treatment with Trichoderma filtrate

Observation of the number of colonies was carried out by counting the number of X. Axanopodis pv. allii colonies by using colony counter, observations carried out at 12, and 24 hours after inoculation.

Results and Discussion

Growth inhibition of X.axanopodis pv. allii that treated with Trichoderma filtrate

In general, secondary metabolites of Trichoderma spp could form a clear zone for inhibition of X. axanopodis pv. allii growth. The area of clear zone is different between isolates and concentrations (Table 1).

The formation of a clear zone indicates that the secondary metabolites produced by Trichoderma spp contains anti-bacterial compounds. T. viride and T. harzianum isolates form higher clear zones compared with Trichoderma PP3. According to Naher et al (2012) some secondary metabolites produced by Trichoderma spp such as polyketides, pyrones, and terpenes act as antibacterial and anti fungal. Basiria et al (2017) reported that T. harzianum (1) and T. viride could inhibit the growth of gram +
**Staphylococcus aureus** and gram negative *Escheria coli*.

The number of *Xanthomonas axanopodis pv.alii* colonies treated with the *Trichoderma* spp. filtrate

The number of *X. axanopodis pv.alii* colonies with the treatment with various concentrations of *Trichoderma* spp. showed significant differences between 12 hours and 24 hours incubation (Table 2 and 3).

*T. harzianum* filtrate showed the better inhibition of *X. axanopodis pv.alii* colonization growth than *T.viride* filtrate and *Trichoderma* PP3. The treatment of *T. harzianum* filtrate with the concentration of 25% could reduce the number of *X. axanopodis pv.alii* colonies compared with without filtrate (control). Increased the concentration of *Trichoderma* spp. filtrate 50% and 100% the growth of *X. axanopodis pv.alii* colonies becomes zero or *X. axanopodis pv.alii* could not grow. This showed that the secondary metabolites produced by *T. harzianum* contain anti-bacterial compounds that could inhibit the growth of *X. axanopodis pv.alii*. Leelavathy *et al.*, (2014) reported that the secondary metabolites or crude extracts of *T. harzianum* could inhibit the growth of various pathogenic bacteria *Staphylococcus aureus*, *E coli*, *Klebsiella*, effective concentration of 100 µl / ml aquades.

The numbers followed by the same lowercase letter on the same lane are not significantly different according to DMNRT level 5%

The secondary metabolites produced by *T. viride* at the concentration of 25% were not able to inhibit the growth of *X. axanopodis pv. alii*. This can be seen in the incubation period of 12 hours the number of *X. axanopodis pv. alii* colonies was the same as the control treatment, namely 33.66 $10^4$sel / ml suspension. This shows that the concentration of 25% did not affect the growth of *X. axanopodis pv. alii*. Increasing the concentration 50% - 75% caused a decrease the growth of *X. axanopodis pv. alii* to 45.66 and 24.66 cells / ml suspension and at concentration 100% *X. axanopodis pv. alii* growth to be zero. Basiriya et al., (2017) report that secondary metabolites (crude extract) of *T. harzianum* and *T. viride* indigenees mangrove rhizosphere were the good isolates inhibiting the growth of *S.aereus, E. coli* and *Pseudomonas auregenesa*.

In conclusion, *Trichoderma* pp. filtrate could inhibit the growth of *X. axanopodis pv. alii*. The higher of concentration the more depressed the pathogen growth. The interaction between the filtrate and the concentration indicated that the filtrate of *T. harzianum* with a concentration of 100% could inhibit the total growth of *X. axanopodis pv. alii*
