The field experiment was carried out at Research farm, Department of Agronomy, Vasantrao Naik Marathwada krishi Vidyapeeth, Parbhani during Kharif, 2018 with an object to find out the effect of various agronomic practices for rain water conservation on growth and yield of rainfed Bt. cotton. The experiment was laid out in randomized block design, replicated thrice with seven treatments. Treatments adopted were T1 - Opening furrow (Every row) 30 DAS, T2 - Opening furrow (Alternate row) 30 DAS, T3 - Straw mulching 30 DAS, T4 - Application of herbicide (Pyriithiobac sodium PE + POE), T5 - Application of Superabsorbent @ 5 kg ha\(^{-1}\), T6 - Intercropping (Cotton + soybean (1:2)), T7 - Control (No moisture conservation practices). seed cotton yield (kg ha\(^{-1}\)) (2116.41), cotton stalk yield (kg ha\(^{-1}\)) (3072.58), biological yield (kg ha\(^{-1}\)) (5188.99), harvest index (40.78 %) and rain water use efficiency (3.76 mm) were recorded significantly in treatment T1 - Opening furrow (Every row) 30 DAS.

**Introduction**

Cotton is the most important fiber crop not only India but of the entire world. It provides the basic raw material to cotton textile industry. Cotton seed contains 15 – 20 per cent oil and is used as vegetable oil and soap industries. After extraction of oil, the left over cake is rich in protein and used as cattle feed. Besides its vital role in national economy, its contribution in the foreign exchange is tremendous, nearly one third of India’s export earnings are from textile sectors of which cotton alone constitutes nearly 70 per cent of raw material and provides employment to 60 million people. Cotton is cultivated both as irrigated and rainfed. In marathwada region cotton under rainfed conditions have to pass through at least one dry spell during its complete growth period, this leads to water stress which adversely effect on growth and development of plant (Sinclair, 2005). Rainfed agriculture has the problem of low productivity due to low moisture in *Rhizosphere* during dry spell. Appropriate moisture conservation measures are therefore necessary for improving soil moisture content and soil fertility (Surakod, Itnal 1997 and Patil, 1998).

Water use efficiency by crops can be improved by selection of crops and cropping...
systems based on available water supplies and increasing seasonal evapo-transpiration (ET) (parihar 2000). Seasonal evapo-transpiration is a measure of consumptive water use by the crops. Increasing the transpiration (T) component of evapo-transpiration (ET) results in higher utilization of water by the crops to increase the productivity. The rate of development of crop canopy and root system and the extent of soil wetting determine the relative fraction of ET lost as evaporation (E) or Transpiration (T). Seasonal evapotranspiration can be increased by selection of irrigation method, irrigation scheduling, tillage, mulching and fertilization (Saini and Chandra, 2010).

In many regions of India, expensive and energy consuming tillage operations, declining soil fertility and soil moisture limitation are major constraint for agricultural crop production. In rainy (kharif) season crops are dependent of rainwater while winter (rabi) season crops are dependent on conserved soil moisture (Dhar et al., 2008). The yield increase was correlated with increase in water contents in soil due to decrease in evaporation (Chuadhary et al., 2012).

The systems of managing crop residue on the soil surface or its incorporation need to be adopted for rainfed crops in India (kumar et al., 2006) with minimum or no tillage these are crucial in efficiently saving more precipitation for crop production. It is hypothesized that, cotton crop needs optimum soil moisture for better boll development hence, residual soil moisture which is conserved by following moisture conservation practices would enhance crop yield as well as water use efficiency. In this view the present study was planned to investigate the effect of different conservation agronomic practices on growth and yield of cotton under rainfed situations

Materials and Methods

A field experiment was conducted during Kharif season of 2018 at the research farm, Department of Agronomy, Vasantrao Naik Marathwada krishi Vidyapeeth, Parbhani (Maharashtra) geographically Parbhani is situated at 19°16’ North latitude and 76°47’ East longitude and at 409 altitude above sea level in Marathwada division encompassed by 17°35’ to 24°40’ North latitude and 74°49’ to 78°15’ East longitude geographical boundaries. Parbhani comes under subtropical climate with average annual precipitation of 885 mm distributed over 57 rainy days. The experimental field was leveled and soil was well drained, clayey in texture, medium in nitrogen, low in phosphorus and rich in potassium and slightly alkaline in reaction. During Kharif 2018-19, rainfall received 727 mm out of which effective rainfall was 562 mm. The experiment was laid out in randomized block design, replicated thrice with seven treatments. moisture conservation treatment for enhancing rain water use efficiency adopted for Bt. cotton (Ajeet-155) were T₁ - Opening furrow (Every row) 30 DAS, T₂ - Opening furrow (Alternate row) 30 DAS, T₃ - Straw Mulching 30 DAS, T₄ - Application of herbicide (Pyrithiobac sodium PE + POE), T₅ - Application of Superabsorbent @ 5 kg ha⁻¹, T₆ - Intercropping (Cotton + soybean (1:2)) and T₇ – No moisture conservation practices (Control). Rainfed Bt. cotton was dibbled on spacing of 150 x 30 cm on 3rd July 2018. Fertilizer dose of 120:60:60 Kg NPK/ha was administrated with nitrogen split of 50 % N at the time of sowing and remaining 50% N at 30 DAS. Integrated plant protective measures were followed for control of pest and diseases are adopted. Five plants in each treatment in the net plot area were selected at random and tagged for biometric observations. The statistical analysis was done as per procedure suggested by Panse and Sukhatme (1967).
Effective rainfall

Water in the root zone is measured by sampling and oven drying the soil before and after every shower of rain. The increase in soil moisture, plus evapo-transpiration loss (ETa) from the time the rain starts until the soil is sampled is the amount of effective rainfall. After heavy rainfall, evapotranspiration can be assumed to be at the potential rate during the short period from cessation of rainfall until the sampling time. This can be taken as 0.4 to 0.8 times the evaporation value of the class A Pan.

\[ ER = M_2 - M_1 + Kp \times Ep \]

Where,

- \( ER \) = Effective rainfall
- \( Ep \) = Class a Pan Evaporation value
- \( M_1 \) & \( M_2 \) = Moisture status in the effective root zone before and after rain respectively.
- \( Kp \) = Pan coefficient.

Harvest index

The harvest index is the ratio between seed cotton yield and the biological yield at harvest (Jain, 1972). It was calculated by the formula given below.

\[ \text{Harvest index} = \frac{\text{Economic yield}}{\text{Biological yield}} \times 100 \]

Gross monetary return (GMR)

The gross monetary returns (₹ ha\(^{-1}\)) from cotton crop were worked out by considering the seed cotton yield from different treatments and prevailing market price in both the seasons.

\[ \text{GMR} = \text{Seed cotton yield} \times \text{MSP} \]

Where,

- \( \text{GMR} \) = Gross monetary return
- \( \text{MSP} \) = Minimum support price (₹ ha\(^{-1}\))

Net monetary return (NMR)

The Net monetary returns were worked out by subtracting the total cost of cultivation from the gross monetary return for the corresponding treatments.

\[ \text{NMR} = \text{Gross monetary return} - \text{Cost of cultivation} \]

Benefit cost ratio

The benefit cost ratio was worked out by using following formula.

\[ \frac{\text{Gross returns}}{\text{Benefit – cost ratio}} = \frac{\text{Gross returns}}{\text{Cost of cultivation}} \]

Results and Discussion

The effect of different agronomic practices on yield contributing characters and yield was observed to be significant.

Yield attributing traits

The highest number of picked bolls plant\(^{-1}\) were observed in treatment Opening furrow (Every row) 30 DAS (T\(_1\)) which was followed by (T\(_2\)) i.e. Opening furrow (Alternate row) 30 DAS, (T\(_3\)) Straw mulching 30 DAS, (T\(_4\)) Application of herbicide (Pyritioback sodium PE+POE) and (T\(_5\)) Application of Superabsorbent @ 5 Kg ha\(^{-1}\). In (T\(_6\)) Intercropping (Cotton + soybean (1:2)) and (T\(_7\)) control (Recommended practices) recorded lowest number of picked bolls per plant were noticed. Similar result was reported by Saravanana et al., (2012), Nehra and yadav (2013) and Ganpati et al., (2018).

The data presented in table 1 revealed that the
treatment (T₁) i.e. Opening furrow in (Every row) 30 DAS recorded the highest weight of bolls per plant (3.49) which was at par with treatment (T₂) Opening furrow in (Alternate row) and (T₃) Straw mulching 30 DAS and found significantly superior over rest of the treatment. Similar observations were reported by Paslawar and Deota (2015).

**Yield**

Data regarding mean seed cotton yield (kg ha⁻¹), cotton stalk yield (kg ha⁻¹), biological yield (kg ha⁻¹), harvest index (HI) (%) and rain water use efficiency (Kg ha⁻¹ mm⁻¹) of rainfed Bt. cotton as influenced by different treatments are presented in Table 2.

**Seed cotton yield (Kg ha⁻¹)**

The data on mean seed cotton yield (Kg ha⁻¹) as influenced by different treatments is presented in table 2. The mean seed cotton yield was 1674.23 Kg ha⁻¹. Treatment (T₁) Opening furrow (Every row) 30 DAS recorded highest seed cotton yield (2116.41 Kg ha⁻¹) which was at par with (T₂) Opening furrow (Alternate row), (T₃) straw mulching, and significantly superior over rest. Control i.e. (T₇) recorded the lowest seed cotton yield (1311.84 Kg ha⁻¹). This result supported with findings by Halemani et al., (2004), Rajendran et al., (2011) and Tayade and Meshram (2013).

**Cotton stalk yield (Kg ha⁻¹)**

The data on mean cotton stalk yield (Kg ha⁻¹) as influenced by different treatments is presented in Table 2. The mean cotton stalk yield was 2843.90 Kg ha⁻¹. Treatment (T₁) Opening Furrow (Every row) 30 DAS recorded highest cotton stalk yield (3072.58 Kg ha⁻¹) which was at par with (T₂) Opening furrow in (Alternate row) 30 DAS, (T₃) straw mulching 30DAS, (T₄) application of herbicide (Pyrithioback sodium PE + POE) and (T₅) application of Superabsorbent @ 5 Kg ha⁻¹ and significantly superior over rest. Similar results were observed by Halemani et al., (2004), Rajendran et al., (2011) and Tayade and Meshram (2013).

**Biological yield (Kg ha⁻¹)**

The data on mean biological yield (Kg ha⁻¹) as influenced by different treatments were present in table 2. The mean Biological yield was (4514.18 Kg ha⁻¹). Treatment (T₁) Opening Furrow (Every row) 30 DAS recorded highest biological yield (5188.99 Kg ha⁻¹) whereas at par with (T₂) Opening furrow (Alternate row) 30 DAS, (T₃) straw mulching 30 DAS, (T₄) Application of herbicide (Pyrithioback sodium PE + POE and (T₅) Application of Superabsorbent @ 5 Kg ha⁻¹, and significantly superior over (T₆) i.e. Intercropping (Cotton + soybean (1:2)) and control (T₇). Lowest biological yield of (4212.65 Kg ha⁻¹) was recorded by control (T₇). This result supported with findings by Paslawar and Deotalu (2015) and Ganpathi et al., (2018).

**Harvest Index (%)**

The data on mean harvest index (%) is presented in Table 2. Harvest index did not show much variation and ranged in between 31.14 to 40.58. The mean harvest index (%) was (36.82%). Opening furrow (Every row) 30 DAS (T₁) treatment recorded highest harvest index (40.78%).

**Rain water use efficiency (Kg ha⁻¹ mm⁻¹)**

The data on Rain water use efficiency is presented in Table 2. Highest rain water use efficiency (3.76 kg ha⁻¹ mm⁻¹) was recorded by opening furrow every row and least was recorded by control (2.33 kg ha⁻¹ mm⁻¹). The increase in rain water use efficiency by
various agronomic practices indicates more conservation of rain water. These results are in conformity with - Ugale et al., (2000).

**Economics**

Data on mean gross monetary returns (GMR) (र. ha\(^{-1}\)), cost of cultivation (COC) (र. ha\(^{-1}\)), net monetary returns (NMR) (र. ha\(^{-1}\)) and benefit: cost ratio (B: C ratio) of rainfed Bt. cotton production system as influenced by different treatments are presented in Table 3.

**Gross monetary return (र. ha\(^{-1}\))**

Data on gross monetary return as influenced by various treatments presented in Table 3. The mean gross monetary return was 93418.57 र. ha\(^{-1}\). Treatment (T\(_1\)) Opening furrow (Every row) 30 DAS recorded highest gross monetary return (112067.70 र. ha\(^{-1}\)) which was at par with (T\(_2\)) Opening furrow (Alternate row) 30 DAS and (T\(_3\)) Straw mulching 30 DAS, and significantly superior over rest of the treatments. Control (T\(_7\)) treatment recorded the lowest gross monetary return (70460.54 र. ha\(^{-1}\)). Similar kinds of observations were recorded by- Gaidhane et al., (2007), Narayana et al., (2011), Patode et al., (2017) and Basediya et al., (2018).

**Net monetary return (र. ha\(^{-1}\))**

Data on net monetary return as influenced by various treatments presented in table 3. The mean net monetary return recorded was (44253.22 र. ha\(^{-1}\)). Treatment (T\(_1\)) Opening furrow (Every row) 30 DAS recorded highest net monetary return (58761.01 र. ha\(^{-1}\)) which was at par with (T\(_2\)) Opening furrow (Alternate row) 30 DAS and (T\(_3\)) Straw mulching 30 DAS, and significantly superior over rest of the treatments.

Control (T\(_7\)) treatment recorded the lowest net monetary return (25894.98 र. ha\(^{-1}\)). Similar kinds of result were recorded by- Narayana et al., (2011), Tayade and Meshram (2013) and Basediya et al., (2018).
Benefit: Cost ratio (B: C)

Data on benefit cost ratio influenced by various treatments presented in Table 3. The mean benefit cost ratio was (1.89). Treatment (T₁) and opening furrow every row recorded the highest benefit cost ratio is (2.1) application of herbicide (Pyri thiobioc acid sodium PE + POE) B:C Ratio recorded (2.01) due to its lower cost of cultivation. Control (T₇) treatment recorded the lowest benefit cost ratio of (1.58). Similar kinds of observations were recorded by- Narayana et al., (2011) and Basediya et al., (2018).

In conclusion the agronomic measures for moisture conservation in rainfed Bt. cotton have significant influence on the growth, yield, productivity and economics among the various treatments. It can be concluded that, all moisture conservation measures have better effect on growth and yield as compared to control.

Highest seed cotton yield, biological yield, harvest index, rain water use efficiency, GMR, NMR and B:C ratio of rainfed Bt. cotton is achieved through Opening of furrow in (Every row) 30 DAS followed by Opening furrow (Alternate row) 30 DAS and Straw mulching 30 DAS due to rain water and moisture conservation.
