ABSTRACT

The effect of exogenous application of 28-homobrassinolide (HBL) on maize seed germination and seedling growth under salt and /or cadmium stress was studied. The seeds exposed to NaCl and/or Cd exhibited a significant decline in germination, seedling length and biomass growth. However, the follow up treatment with HBL detoxified the stress generated by NaCl and/or Cd and significantly improved the above parameters. The NaCl and/or Cd increased electrolyte leakage, lipid peroxidation and hydrogen peroxide content. However, HBL application significantly decreased the hydrogen peroxide levels and membrane damage in maize seedlings under salt and/or Cd stress. The antioxidative enzymes and the level of proline exhibited a significant increase in response to HBL as well as to NaCl and/or Cd stress.

28-homo brassinolide, Antioxidative enzymes, Cadmium stress, Germination, Oxidative stress, Salt stress

Introduction

Salinity is one of the most important abiotic stresses reducing crop production. In the world, more than 20% of the irrigated arable land in arid and semi-arid regions has been already salt-affected (Huang et al., 2007). In developing countries cadmium (Cd) contamination in arable soils and surface water has become severe due to improper management of waste and application of chemicals containing Cd, in addition to salinity (Helal et al., 1999). In arid and semi-arid regions, bio-solids may be used on saline soils in order to improve soil quality which results in heavy metals contamination such as Cd, (Weggler-Beaton, et al., 2000). Moreover, soil salinity has been shown to increase Cd concentration in crops grown on soils fertilized with phosphorous (P) fertilizers containing Cd (McLaughlin et al., 1994). In the past two decades, phosphorous fertilizers were extensively applied to these saline soils to alleviate salt stress to crops (Deng et al., 2002). As a result, Cd content in these soils has been dramatically increased. It has been well documented that salt and Cd stress in combination caused higher plasma membrane permeability and enhanced the production of reactive oxygen species in wheat (Muhling and Lauchli, 2003). Excess reactive oxygen species accumulation in cells may expose the plant to severe oxidative stress, causing growth inhibition even death. On the other hand, in plant cells, an antioxidant defense
mechanism has been developed for protection against reactive oxygen species (Ramakrishna and Rao, 2013). One of the protective mechanisms is the enzymatic antioxidant system, which involves the sequential and simultaneous action of a number of enzymes including superoxide dismutase (SOD) and peroxidase (POD). In fact, activities of antioxidant enzymes are inducible by oxidative stress due to exposure to abiotic or biotic stresses (Shafi et al., 2010). Peroxidase and SOD activity increased distinctly in barley plants subjected to salinity stresses and/or cadmium (Huang et al., 2006). Thus, interaction of Cd and salinity should be taken into consideration where both stresses are expected to impact crop growth and yield.

Brassinosteroids (BRs) are polyhydroxylated steroid hormones synthesized in all tissues that are involved in regulation of broad spectrum of processes i.e. cell expansion, pollen tube growth, vascular differentiation, senescence, photomorphogenesis and fruit development (Rao et al., 2002; Vardhini et al., 2010). BRs bind to the extracellular domain of a receptor kinase, brassinosteroid insensitive1 (BRI1), leading to sequential phosphorylation and dephosphorylation of signaling components and finally regulate gene expression (Clouse, 2011; Yang et al., 2011). Recently, BRs have gained more attention as lots of studies indicated that BRs modulate plant metabolic response to environmental biotic and abiotic stresses, and these physiological processes include salt and drought stress tolerance, heavy metal stress resistance, pathogen resistance (Vardhini et al., 2010; Ramakrishna and Rao 2014) as well as herbicide and pesticide tolerance (Bajguz and Hayat 2009; Xia et al., 2009). The question how BRs may impact such a diverse physiological processes remained unanswered. Owing to obvious evidence of adverse effects of salt and Cd stress on plant growth, it was hypothesized that the novel plant bio-regulator 28-homobrassinolide (HBL) used in this study can overcome damaging effects of salt and Cd stress on maize plants. Therefore, the study aims to examine whether or not could alleviate the injurious effects of salt and Cd stress on germination and growth by improving the antioxidant enzyme activities involved in stress tolerance.

Materials and Methods

Plant material and chemicals
The seeds of maize (Zea mays L.) were procured from National Seed Corporation, Hyderabad, India. 28-homobrassinolide (HBL) employed in the present study was procured from Sigma chemicals.

Standardization and selection of NaCl and Cadmium concentrations
To induce salt stress, NaCl salt was used. The experimental concentration was selected based on the IC₅₀ value using different concentrations of NaCl i.e. 50, 100, 150, and 200 mM and 150 mM was selected as workable concentration. On the basis of screening experiments with varying concentrations (0.1, 0.5, 1.0, 1.5 and 2.0 mM) of cadmium [CdCl₂·2H₂O], 1 mM Cd²⁺ was selected based on IC₅₀ values where the germination and seedling growth was found inhibited substantially but not completely and Cd dose is under the safe limit (WHO, 2007).

Growth conditions and treatments
Seeds of maize were surface sterilized with 0.5% (v/v) sodium hypochlorite from commercially available (4% NaOCl) and washed thoroughly with several changes of sterile distilled water. Preliminary experiments were conducted to choose
hormone concentration using a wide range of concentrations of HBL (0.25, 0.5, 1.0, 2.0, 3.0 and 4.0 µM). Based on the growth response test two concentrations of HBL, i.e., 1.0 and 2.0 µM were selected where significant growth promotion was observed (data not shown). The treatments were divided into eight groups: (i) Distilled water (Control) (ii) 1.0 µM and 2.0 µM 28-homobrassinolide solutions (iii) NaCl (150 mM) (iv) Cd Cl₂ (1mM Cd²⁺) (v) NaCl+CdCl₂ (vi) NaCl supplemented with 1.0 and 2.0 µM 28-homobrassinolide solutions (vii) CdCl₂ supplemented with 1.0 and 2.0 µM 28-homobrassinolide solutions (viii) NaCl+CdCl₂ supplemented with 1.0 and 2.0 µM 28-homobrassinolide solutions. Twenty seeds from each treatment were placed in each of 9 cm sterile petri dishes layered with Whatman No.1 filter paper. The petri dishes were supplied with 5 ml of respective test solutions. The seeds were allowed to germinate in dark at 20 ±1°C. 3 ml more of test solutions were added on the 4th day of the experiment.

**Germination percentage and morphological parameters**

Number of seeds germinated was recorded at the end of 12, 24 and 48 hours under safe green light. Emergence of radicle was taken as the criteria for germination. The number of seeds germinated was counted in each treatment and percentage of seed germination was calculated by following:

$$\text{No. of seeds germinated / total no. of seeds} \times 100.$$

The growth of 7 day-old maize seedlings was assessed by recording the length, fresh weight (FW) and dry weight (DW). Five seedlings one each from each Petri dish were selected randomly.

**Lipid peroxidation:** One gram of seedling material was macerated in 5 ml of 0.1% (w/v) TCA (Trichloroacetic acid). The homogenate was centrifuged at 10,000 X g for 5 minutes. For 1 ml of the aliquot of the supernatant, 4 ml of 20 % TCA containing 0.5% TBA was added. The mixture was heated at 95°C for 30 minutes and cooled quickly in ice bath. The absorbance was measured at 532 nm and 600 nm. The concentration of malondialdehyde (MDA) was calculated by using extinction coefficient of 155 mM⁻¹ cm⁻¹ (Heath and Packer 1968).

**Hydrogen peroxide:** Isolation was made from 0.5 g of the treated seedling material in ice-cold acetone. By addition of 50% (w/v) titanyl sulphate and conc. NH₄OH solution, the peroxide-titanium complex was precipitated. The precipitate was dissolved in 15 ml of 2M H₂SO₄, making the final volume to 20 ml in cold water. The absorbance of the resultant solution was read at 415 nm. The H₂O₂ content was calculated from a standard curve prepared in similar way (Mukherjee and Choudari, 1983).

**Electrolyte leakage:** was measured using electrical conductivity meter (Systroni-304, India) as described by Lutts *et al.* (1996). Seedlings were washed with deionized water to remove surface adhered electrolytes. After drying with filter paper, 1 g fresh weight of seedlings were immersed in 20 mL deionized water and incubated at 25 °C on rotary shaker for 24 hours. After 24 h, electrical conductivity (EC1) of the bathing solution was recorded. These seedling samples were then autoclaved at 120 °C for 20 min to completely kill the tissues and release all electrolytes. Samples were then cooled to 25 °C and the final electrical conductivity (EC2) was measured. The electrolyte leakage (EL) was expressed following the formula:

$$\text{EL} (%) = \left( \frac{\text{EC1} \times \text{EC2}}{\text{EC2}} \right) \times 100.$$

**Assay of the antioxidant enzymes**

Fresh seedling material (1 g) was
homogenized in 50 mM Tris-HCl (pH 7.5) with addition of 40 mM phenyl methyl sulfonyl fluoride (PMSF) and 0.2 mM EDTA, 2% (w/v) polyvinyl pyro pyrolidone (PVPP). The extract was centrifuged at 15,000 X g for 20 min and the resultant supernatant was used for measuring the following enzyme assays. The amount of protein in the enzyme extract was calculated according to Lowry and others (1951).

**Catalase:** (CAT, E.C.1.11.1.6.) activity was determined following Aebi (1974). The rate of H$_2$O$_2$ decomposition at 240 nm was measured spectrophotometrically and calculated using a molar extinction coefficient of 45.2mM$^{-1}$ cm$^{-1}$. The reaction mixture consisted of 50 mM phosphate buffer, 0.1mM H$_2$O$_2$ and enzyme extract. One unit of catalase activity was assumed as the amount of enzyme that decomposed 1 µmol of H$_2$O$_2$ per mg of soluble protein per minute at 30 $^\circ$C.

**Peroxidase:** (POD, E.C.1.11.1.7) activity was assayed by employing the procedure of Kar and Mishra (1976). To 0.5 ml of enzyme extract, 2.5 ml of 0.1 M phosphate buffer (pH 7), 1 ml of 0.01 M pyrogallol and 1 ml of 0.005 M H$_2$O$_2$ were added. A blank was prepared with 0.5 ml of enzyme extract, 3.5 ml of 0.1 M phosphate buffer and 1 ml of 0.005 M H$_2$O$_2$. After 5 minutes of incubation at 25 $^\circ$C, the reaction was stopped by adding 1 ml of 2.5 N H$_2$SO$_4$. The amount of purpurogallin formed was estimated by measuring the absorbance at 420 nm against a blank. The enzyme activity was expressed as Units mg$^{-1}$ protein.

**Superoxide dismutase:** (SOD, E.C 1.15.1.1) activity was assayed by measuring its ability to inhibit the photochemical reduction of NBT (Nitroblue tetrazolium) of Beauchamp and Fridovich (1971). A 3 ml of reaction mixture contained 40 mM phosphate buffer (pH 7.8), 13 mM methionine, 75 µM NBT, 0.1 mM EDTA, 0.1 ml of enzyme extract and 2 µM riboflavin. Riboflavin was added at the end. The reaction mixture was exposed to 15 watt fluorescent tubes and the decrease in the absorbance of the reaction mixture was read at 560 nm. Fifty percent inhibition was considered as one enzyme unit.

**Ascorbate peroxidase** (APX; E.C 1.11.1.11) was assayed by the method of Nakano and Asada (1981). The reaction mixture contained 1.5 ml of 50 mM sodium phosphate buffer (pH 7), 0.2 mM EDTA, 0.5 ml of 0.5 mM ascorbic acid, 0.5 ml 0.5 mM H$_2$O$_2$ and 0.5 ml of enzyme sample. The activity was recorded as the decrease in absorbance at 290 nm for 1 minute and the amount of ascorbate oxidized was calculated from the extinction coefficient of 2.6 mM$^{-1}$ cm$^{-1}$.

**Glutathione reductase** (GR; EC 1.6.4.2) activity was performed according to Jiang and Zhang (2002). The reaction mixture contained 500 µl of sodium phosphate buffer (pH 7.0), 100 µl each of 10 mM GSSG, 1 mM NADPH and 180 µl of distilled water. The reaction was started by addition of enzyme extract and NADPH oxidation was recorded as the decrease in absorbance at 340 nm for 1 min. The activity was calculated using the extinction coefficient of NADPH 6.22 mM$^{-1}$ cm$^{-1}$.

**Free Proline**

Seedling material (0.5 g) was homogenized with 10 ml of 3 % (w/v) sulfo salicylic acid and the homogenate was filtered through Whatman No. 2 filter paper. The supernatant was taken for proline estimation. The reaction mixture was composed of 2 ml of plant extract, 2 ml of acid ninhydrin reagent and 2 ml of glacial acetic acid. The test tubes containing above mixture were heated in a boiling water bath for one hour. The
reaction was terminated in an ice bath followed by addition of 4 ml of toluene. The contents were shaken vigorously and then allowed to separate into phases. The chromophase containing upper toluene phase was carefully taken out with the help of a pipette and the absorbance was taken at 520 nm. The amount of proline present was quantified with the help of proline standard graph (Bates et al., 1973).

**Ascorbic acid (AsA): and glutathione (GSH) levels**

Fresh seedlings (0.2 g) were homogenized in 5 ml of 5% (v/v) m-phosphoric acid. The homogenate was centrifuged at 12,000 X g for 15 min. For determination of total ascorbate, 0.1 ml supernatant and 0.5 ml of 100 mM KH₂PO₄ buffer (pH 7.4) containing 5 mM EDTA and 0.2 ml 10 mM DTT (dithiothreitol) were mixed and incubated at room temperature for 15 min. Then 0.2 ml 0.5% (w/v) N-ethylmaleimide was added to remove excess DTT, and then 0.8 ml 10% (w/v) TCA, 0.8 ml 44% (v/v) o-phosphoric acid, 0.8 ml a,a´-dipyridyl in 70% (v/v) ethanol and 0.4 ml 30 g l⁻¹ FeCl₃ were added and well mixed in sequence. AsA was assayed in a similar manner except that 0.2 ml of ddH₂O was substituted for DTT. The absorbance of the mixture at 525 nm was recorded after incubation at 40 ºC for 1 h (Hodges et al., 1996).

One gram of seedlings were homogenized with 10 ml Tris EDTA (pH 8.2) and centrifuged at 25,000 X g for 30 minutes at 4⁰C. From the homogenate 300 µl was pipetted into 1 ml of tube to which 60 µl of 25% phosphoric acid is added and kept in ice for 5 minutes, centrifuged at 25,000 X g for 30 minutes at 4⁰C. Supernatant was collected for the estimation of GSH. For measurement of GSH, 450 µl of cold phosphate EDTA buffer (pH 8) was added to 50 µl of supernatant and mixed thoroughly. Aliquots (25 and 50 µl) was taken into 5 ml test tube and made up to 100 µl with cold glass distilled water. Phosphate EDTA buffer (1.8 ml) was added to the tube and mixed and 100 µl of OPT (O-phthalaldehyde) solution was then added and after thorough mixing, incubated at room temperature (25⁰C) for 15 minutes (Hissin and Hilf 1976).

**Statistical analysis**

The results presented are the mean values of 5 replicates. The data analyses were carried out using one-way analysis of variance (ANOVA) followed by Post Hoc Test (Multiple Comparisons) using SPSS (SPSS Inc., Chicago, IL, USA). The differences were considered significant if p was ≤ 0.05. The mean values were compared and lower case letters are used in figures/table to highlight the significant differences between the treatments.

**Results and Discussion**

The stress generated by NaCl and/or Cd significantly reduced the germination percentage of maize seeds in comparison to their respective controls (Table 1). However, the inhibitory effect of NaCl and/or Cd stress on seed germination was significantly ameliorated by addition of HBL. The NaCl and/or Cd stressed seedlings treated with HBL, the percentage of seed germination approached that of unstressed control treatments at 2 µM concentration. The treatment of HBL alone exhibited enhanced germination percentage as compared to the untreated control, with maximum increase in seed germination percentage was noted for seedlings applied with 2µM concentrations.

The presence of NaCl and/or Cd significantly reduced the growth (seedling length, fresh weight and dry weight in maize seedlings (Table 2). The combined effect of
these two stress factors was more toxic compared to their individual ones. Compared to control, the above mentioned parameters were decreased by 47.2, 33.2 and 53.3% respectively. However, the application HBL, in the absence of NaCl and/or Cd stress increased the growth that was significantly higher than the control seedlings. HBL treatment also enhanced the growth of maize seedlings grown under NaCl and/or Cd stress and the values were considerably higher than those of the seedlings grown under stress alone.

In the present study, NaCl and/or Cd stress resulted in oxidative stress as reflected by increased levels of H$_2$O$_2$ (33.8%), MDA content (90.8%) and electrolyte leakage (48.7%) in maize seedlings (Table 3). Supplementation of HBL alleviated the oxidative stress by significantly depressing the H$_2$O$_2$, MDA and ELP levels by 22.3, 40 and 25.2% respectively. There was no significant change in the levels of H$_2$O$_2$, MDA, ELP in seedlings receiving HBL alone treatments compared to the unstressed control seedlings.

The antioxidative enzymes, CAT, SOD, POD, APX and GR exhibited an increasing trend in response to HBL and NaCl and/or Cd treatment (Table 4 and 5). The HBL treatment caused a significant increase in the activities of all the enzymes. The seedlings exposed to NaCl alone stress also possessed an increased level of these enzyme activities but Cd reduced the GR activity (Table 5). However, in association with NaCl or HBL treatment, it also improved the activities of all the above mentioned enzyme activities. Maximum activities of these enzymes recorded in maize seedlings exposed to combined NaCl and/or Cd stress and subsequently received HBL treatment at 1 µM concentration.

The level of proline exhibited an increase in response to NaCl and/or Cd stress, in seedlings compared to control (Table 5). Application of HBL to NaCl and/or Cd stressed seedlings, elevated the quantity of proline in maize with maximum quantity being at 2 µM concentrations. HBL alone treatments also resulted in considerable increase in the quantity of free proline in maize seedlings.

In the presence of NaCl and/or Cd stress the content of ASA was reduced considerably, whereas GSH content was increased significantly in maize seedlings (Table 6). However, the exogenous application of HBL to maize seedling under NaCl and/or Cd stress, the contents of both ASA and GSH were improved significantly. HBL alone treatments also accounted for significant enhancement of ASA and GSH contents in maize seedlings.

The present investigation shows that, the germination of maize seeds was dramatically suppressed by NaCl and/or Cd stress (Table 1). Further, the results showed that NaCl and/or Cd stress exerted strong inhibiting effect on growth and development as reflected by significant reduction of seedling length, fresh weight and dry weight as compared to the control (Table 2). However, HBL application reduced the toxic effect of NaCl and/or Cd stress on seed germination and growth.

In NaCl and/or Cd stressed treatments supplemented with HBL, the percentage of seed germination approached to that of unstressed control treatments. Application of HBL significantly alleviated suppression of seedling growth caused by NaCl and/or Cd stress resulted in improved seedling length and biomass indicating the stress alleviation capability of BRs (Table 2). Furthermore, the stress amelioration capability of HBL was found to be dose dependent. Exogenous application of 24-epibrassinolide up
regulated a particular cyclin gene, *CycD3*, which was involved in the cell cycle of *Arabidopsis*, leading to enhanced seed germination by stimulating cell expansion and cell proliferation (Nakaya et al., 2002). Recently, Wang et al. (2011) reported that the inhibitory effect of salinity on seed germination of cucumber (*Cucumis sativus*) seeds was significantly alleviated by addition of 24-EBL. Anuradha and Rao (2007) also observed that exogenous application of 24-EBL and 28-HBL improved the seed germination in radish under Cd toxicity dose dependently. The growth promoting effects of BRs on seedlings under stress conditions might be attributed to their involvement in cell elongation and cell cycle progression as well as regulation of genes encoding xyloglucan endotransglucosylase/hydrolases (XTHs), expansions, glucanases, sucrose synthase and cellulose synthase or by activating the H⁺-ATPase activity (Clouse, 2011).

The values are means ±SE (n = 5); mean followed by the same alphabet in a column is not significantly different at p=0.05 according to Post Hoc test.
A common consequence of most abiotic stresses, including salinity (Hayat et al., 2010) and heavy metal stress (Yadav et al., 2010) is an increased production of reactive oxygen species (ROS). These ROS namely superoxide radical (O$_2^-$), hydroxyl radical (·OH) and hydrogen peroxide (H$_2$O$_2$) are extremely toxic to plants that cause oxidative damage to proteins, lipids and nucleic acids, leading to irreparable metabolic dysfunction and cell death (Sharma and Dietz, 2009). To combat oxidative damage of ROS, plants have antioxidant defense system comprising of enzymes of SOD, CAT, APX and GR, and the non-enzymic constituents such as reduced glutathione (GSH) and ascorbate (ASA) that remove, neutralize and scavenge ROS (Gill and Tuteja 2010). SOD dismutates O$_2^-$ to H$_2$O$_2$ and this is decomposed to water by CAT and POD. GR maintains the pool of glutathione in reduced state, thereby enhances tolerance to oxidative stress (Alscher et al., 2002). In the present study, NaCl and/or Cd stress resulted in oxidative stress as evidenced by increased H$_2$O$_2$ generation, MDA content and electrolyte leakage in maize seedlings (Table 3). However, exogenous application of both HBL dramatically depressed H$_2$O$_2$ and, MDA accumulation there by electrolyte leakage in NaCl and/or Cd stressed maize seedlings, suggesting that BRs helps in the maintenance of membrane integrity against oxidative damage under NaCl and/or Cd stress.

The acceleration of the activities of SOD, CAT, POD and APX were observed in NaCl and/or Cd stressed seedlings. But, the activity of GR exhibited differential response to stress i.e. decreased under Cd stress and increased under NaCl and Cd stress. The supplementation of HBL to NaCl and/or Cd stressed seedlings increased the all enzyme activities (CAT, POD, APX, SOD and GR) in both stressed and unstressed conditions (Table 4 and 5).

Interestingly, exogenous application of HBL increased the ascorbate and glutathione content as well as frees proline levels in maize seedlings under NaCl and/or Cd stress and stress free conditions (Table 6).

The elevation of both enzymatic and non-enzymatic levels upon HBL treatment conferred stress tolerance which manifested in terms of improved growth and biomass production. In consistent with these observations Ali et al., (2008) reported that exogenous application of 24-epibrassinolide enhanced the antioxidative enzymes and proline levels under salinity and/or nickel stress in Brassica juncea. Similarly, enhanced the proline, antioxidant levels and antioxidative enzyme activities in Phseolus vulgaris under salt and cadmium (Rady, 2011), Vigna radiata under salt and temperature (Hayat et al., 2010) and radish under zinc stresses (Ramakrishna and Rao, 2012) upon exogenous application of brassinosteroids were observed. The enhanced antioxidative defense system seems to be the result of de novo synthesis and/or activation of the enzymes, mediated through transcription and/ or translation of specific genes that has added more strength to drought stressed seedlings against oxidative stress.

In conclusion, 28-Homobrassinolide enhanced the level of antioxidant system (SOD, CAT, POD, APX and GR, and levels of proline, ascorbate and glutathione) both under stress and stress free conditions. The influence of HBL on antioxidant system was more pronounced under NaCl and/or Cd stress condition, suggesting that the elevated level of antioxidant system, at least in part, increased the tolerance of maize seedlings to NaCl and/or Cd stress, thus protected from oxidative injury. This further manifested in increased germination, growth and dry mass production of maize seedlings.
